ABSTRACT

Background Persulfate salts are the main cause of occupational asthma (OA) in hairdressers. The aim of this study was to verify whether ammonium persulfate ((NH4)2S2O8, AP) is capable of triggering an asthma-like response in mice.

Methods BALB/c mice were dermally treated on days 1 and 8, with dimethylsulfoxide (DMSO), 1% AP or 5% AP (20 μl/ear). On day 15, the auricular lymph nodes were removed and an in vitro lymphocyte proliferation test (LPT) was performed. AP was tested for its ability to elicit an asthmatic response using a locally developed mouse model of chemical-induced asthma. On days 1 and 8, BALB/c mice received 20 μl AP (5%) or DMSO on each ear. On day 15, they received an intranasal instillation of AP (1%) or saline. Afterwards, ventilatory, inflammatory and immunological parameters were assessed.

Results The LPT showed that in vitro stimulation of lymphocytes with AP leads to specific proliferation of AP-sensitised mice. In vivo, AP induced, in AP-sensitised mice only, an ‘early’ ventilatory response (increased Penh (enhanced pause)) immediately after challenge, and airway hyper-reactivity to methacholine 22 h later. Pulmonary inflammation was mainly characterised by neutrophils (10–15%). AP-sensitised mice showed an increase in total number of T helper (Th) and B lymphocytes together with an increased in vitro secretion of interleukin-4 (IL-4), IL-10 and IL-13 and an increase in total serum immunoglobulin E.

Conclusions In a mouse model, it was confirmed that dermal sensitisation to AP can lead to asthma-like responses after a single administration via the airway.

INTRODUCTION

Occupational exposures are estimated to be responsible for 10–25% of all asthma cases in adults.1 Occupational asthma (OA) is one of the most frequent forms of lung-related occupational diseases in the industrialised world.2 The prevalence of occupational asthma is mostly dependent on the nature of the agents and the exposure concentrations, and less on host-dependent factors such as atopy and smoking status.3 4 Persulfate salts are a well-known cause of OA and, according to French and Catalan registries of OA, persulfates are the second most frequent cause of OA in women.5–7 Persulfate salts are highly reactive low molecular weight chemical compounds that are widely used for various manufacturing processes in the chemical, pharmaceutical, metallurgical, textile, photographic, food and, especially, cosmetic industries.8 These salts are capable of causing immunological sensitisation and subsequent allergic disease, such as contact dermatitis and bronchial asthma, and they are reputed to be the main cause of OA in hairdressers.5–14

The mechanisms by which persulfate salts induce sensitisation and OA in hairdressers remain unknown. Some authors suggested that mast cells and T cells may play a role in the pathogenesis of the asthmatic reactions following inhalation of persulfate salts.3 15 Muñoz et al suggested that this immunological mechanism might be mediated by immunoglobulin E (IgE), since a positive skin prick test to persulfate salts and elevated total serum IgE levels was found in some patients, which was also observed in ~50% of cases published to date.12 13 15–17 However, not all subjects with demonstrated persulfate asthma have a positive skin prick test to persulfates.

Previously, we demonstrated, using the murine local lymph node assay, that ammonium persulfate ((NH4)2S2O8; AP) is a moderate dermal sensitisier.18 In this study, we further investigated the lymphocyte-specific response to AP in an in vitro lymphocyte proliferation test (LPT) and the potential of AP to induce an asthma-like response using a validated mouse model of chemical-induced asthma based on dermal sensitisation and an intranasal challenge.19–21

MATERIALS AND METHODS

Animals Male BALB/c mice (~20 g, 6 weeks old) were obtained from Harlan (Horst, The Netherlands). The mice were housed in filter top cages in a conventional animal house with 12 h dark/light cycles and received lightly acidified water and pelleted food (Trouw Nutrition, Gent, Belgium) ad libitum. All experimental procedures were approved by the local Ethical Committee for Animal Experiments.

Lymphocyte proliferation test

On days 1 and 8, the mice received dermal applications of AP ((NH4)2S2O8, CAS 7727-54-0) (1% or 5%), vehicle (dimethylsulfoxide (DMSO)) (20 μl) or nothing (naïve) on both ears. On day 15, the auricular draining lymph nodes were excised, pooled (five mice) and kept on ice in RPMI-1640 (Invi- trogen, Merelbeke, Belgium). Cell suspensions were obtained by pressing the lymph nodes through a cell strainer (100 μm) and rinsing with 5 ml of RPMI-1640 tissue culture medium. Cells were counted using a Bürker haemocytometer. Lymphocytes were washed twice with 5 ml of tissue culture medium and centrifuged (1000 g, 10 min, 4°C). The pellets

were resuspended in complete tissue culture medium (RPMI-1640 supplemented with 10% heat-inactivated fetal bovine serum, 10 mg/ml streptomycin, 100 IU/ml penicillin) at concentrations of 10^5 cells/ml. One hundred thousand cells were incubated with or without AP (0.001%, 0.01% or 0.01%, dissolved in complete medium) in 200 μl of complete medium with 20 μCi of [methyl-3H]thymidine ([H]TdR, ICN Pharmaceuticals, Asse, Belgium) per well, in 96-well culture plates. After 18 hs, cells were centrifuged at 1000 g for 10 min at 4°C. Supernatants were discarded and the cells were washed twice with phosphate-buffered saline (PBS*) and once with 1 ml of 5% trichloroacetic acid (TCA; Sigma-Aldrich, Bornem, Belgium). The cells were then resuspended in 5% TCA (5 ml) and stored overnight at 4°C. After centrifugation (1000 g, 10 min, 4°C) the pellets were resuspended in 500 μl of 5% TCA and transferred to 5 ml of scintillation fluid (ultima gold, PerkinElmer, Groningen, The Netherlands). The incorporation of [H]TdR was measured by β-scintillation (Beckman LS 5000CE, Irvine, California, USA) and expressed as counts per minute (cpm). Each time, the lymph nodes of five controls or AP-treated mice were pooled and each in vitro AP proliferation assay was performed in five replicates. In total an average (±SD) cpm is calculated.

Mouse model of chemical-induced asthma

On days 1 and 8, the animals received dermal applications of 5% AP or vehicle (DMSO) on the dorsum of both ears (20 μl). On day 15, they received, under light anaesthesia with isoflurane (Forene®, Abbott Laboratories, Oss, Belgium), an intranasal instillation (40 μl) of 1% AP (challenge) or vehicle (saline). Experimental groups are DMSO/SAL, DMSO/AP and AP/AP. The first abbreviation identifies the agent used for the dermal application on days 1 and 8 (sensitisation) and the second abbreviation identifies the agents administered via intranasal instillation on day 15 (challenge).

Each group consisted of 10 animals, five of which underwent a methacholine provocation using whole-body plethysmography, while the other five underwent a methacholine provocation using a forced oscillation technique.

The ventilatory function of each mouse was measured in a whole body plethysmograph (EMKA Technologies, Paris, France) as described previously. The area under the curve (AUC) of Penh (enhanced pause) was calculated against time between 0 and 252 min. Data analysis

All data were normally distributed as assessed by the D’Agostino and Pearson omnibus normality test. All data are presented as mean±SD and were analysed using one-way analysis of variance (ANOVA) followed by a Dunnett posthoc test (Graphpad Prism 4.01, Graphpad Software Inc, San Diego, USA). A level of p<0.05 (two tailed) was considered significant.

RESULTS

Figure 1 shows the cpm in the LPT when 100,000 lymphocytes from the auricular lymph nodes obtained from naïve, vehicle-treated or AP-sensitised (1% or 5%) mice were cultured for 18 h in the presence of [H]TdR and various concentrations of AP.

There were no significant changes in cpm counts when auricular lymphocytes from naïve or DMSO-treated mice were incubated with AP (figure 1A,B), compared with control exposure (0% AP). In contrast, the lymphocytes of mice treated with 1% or 5% AP exhibited significant two- to threefold increases in cpm count upon incubation with 0.0001% and 0.001% AP, compared with the control (figure 1C,D). No proliferation was found with the highest concentration of AP (0.01%).

In the in vivo asthma model an early ventilatory response immediately after intranasal instillation was found in AP-sensitised and challenged mice: Penh (expressed as AUC) of the completely AP-treated mice (AP/AP=71±56, p<0.001) was statistically higher than the Penh of the two control groups (DMSO/AP=17±5 and DMSO/SAL=16±4).

Methacholine airway hyper-responsiveness (AHR) was measured 22 h after the intranasal instillation (figure 2). AHR was determined using the whole-body plethysmograph (Penh,
Figure 1  Lymphocyte proliferation test (LPT) on auricular lymphocytes. A lymphocyte proliferation test was performed on the auricular lymph nodes (ALNs) of naïve mice (A), vehicle (dimethylsulfoxide (DMSO))-treated mice (B), 1% ammonium persulfate (AP)-treated mice (C) and 5% AP-treated mice (D). The ALNs were cultured for 18 h in the presence of [3H] TdR and various concentrations of AP. Means±SD are depicted; the experiment was performed in five replicates. *p<0.05, **p<0.01 compared with the 0% AP control group.

Figure 2  Airway hyper-reactivity (AHR) to methacholine. AHR expressed as Penh (enhanced pause) was measured 22 h after intranasal challenge by whole-body plethysmography (A, B) and AHR expressed as resistance (R) was measured 22 h after intranasal challenge by the forced oscillation technique (C, D). Left panels: mean values of Penh±SD (A) or R±SD (C) with increasing concentrations of methacholine. Right panels: individual values of the area under the curve (AUC) of Penh (B) or R (D). Experimental groups are DMSO/SAL, DMSO/AP and AP/AP. The first abbreviation identifies the agent used for dermal application (days 1 and 8) and the second identifies the agent administered intranasally (day 15). A and C: means±SD, B and D: individual values and group mean. n=4–5 mice per group. *p<0.05, **p<0.01, ***p<0.001 compared with the DMSO/SAL control group. AP, ammonium persulfate; DMSO, dimethylsulfoxide; SAL, saline.

Figure 3  The total and differential BAL cell count. The total number of BAL neutrophils was significantly increased in completely AP-treated (AP/AP) mice, compared with the DMSO/AP and DMSO/SAL groups. Neither eosinophils nor lymphocytes were found in BAL.

Figure 4  Shows the total numbers of CD3+. (T lymphocytes), CD3+CD4+ (T helper (Th) lymphocytes), CD3+CD4+CD25+ (activated–regulatory Th lymphocytes), CD3+CD8+ (cytotoxic T (Tc) lymphocytes) and CD19+ (B lymphocytes) cells in auricular, cervical and mediastinal lymph nodes. In both the auricular and cervical lymph nodes of completely AP-treated mice...
a significant increase was found in both T and B lymphocytes (figure 4B,C), compared with the control groups. The increase in T lymphocytes was a result of a significant increase in all three subpopulations measured (Th, T regulatory (Treg) and Tc lymphocytes). Mediastinal lymph nodes did not show any difference between the three treatment groups, but the numbers were low (figure 4D).

Table 1 shows the concentration of several cytokines measured in the supernatant of auricular, cervical and mediastinal lymphocytes that were cultured for 42 h with ConA. Significantly lower IL-2 concentrations and higher IL-4 concentrations were measured in auricular as well as cervical lymphocytes of the AP/AP group, compared with both control groups (DMSO/AP and DMSO/SAL). A higher amount of IL-10 and IL-13 was found only in auricular lymphocytes of AP/AP mice compared with the DMSO/SAL group.

Figure 5 shows that total serum IgE was increased (3.5- and 2-fold) in the completely AP-treated mice (AP/AP) compared with DMSO/SAL and DMSO/AP mice.

DISCUSSION

Although occupational asthma caused by persulfate salts is relatively frequent in hairdressers, little or no experimental work has been done to understand sensitisation and the mechanisms of this form of chemical-induced asthma. Here, we have demonstrated that lymphocytes obtained from the draining lymph nodes of dermally AP-sensitised mice can be stimulated to
proliferate when challenged in vitro with the sensitising agent (AP). Furthermore, we have shown that in vivo intranasal challenge in such dermally sensitised mice leads to an immediate early ventilatory response, followed by increased reactivity to methacholine 22 h later, which is accompanied by an increase in the number of neutrophils, increased numbers of T and B lymphocytes in auricular and cervical draining lymph nodes and an increase in total serum IgE.

Persulfates are low molecular weight strong oxidising agents that are used by chemical workers and hairdressers mainly for bleaching processes.23 Not only skin diseases such as contact dermatitis, but also respiratory disorders have been reported after exposure to persulfates.10–16 Workers who are exposed to persulfate salts are at high risk of developing OA, although the mechanism of the induction of asthma is not well understood.14 The latency period between the onset of exposure and onset of symptoms, and the type of response observed in challenge tests suggest that persulfate-induced OA is mediated by an immunological mechanism.13 14 24 It is possible that in some patients the mechanism is IgE mediated, since positive skin prick tests to persulfates have been obtained in some studies.12 13 15 16 Wrbitzky et al found, in a study of employees of a persulfate manufacturing plant, that 15% of workers developed a positive skin prick test reaction and these subjects also had a lower lung function.25 Furthermore, elevated total serum IgE levels and anaphylactic reactions upon exposure to persulfates have also been described.8 15 However, non-IgE-mediated mechanisms may also be involved because clinically positive patients do not always have positive skin prick tests. Moreover, Yawalkar et al suggested that T lymphocytes may be directly involved in mediating inflammatory processes in the airways based on the results of lymphocyte proliferation analyses.3

Classically, adverse effects of inhaled chemicals on the respiratory system have been assumed to be induced by inhalation exposure. However, more recent data support the potential for dermal exposure to lead to respiratory tract sensitisation.26 27

Experimental support for such a mechanism has been provided by several research groups, who demonstrated in mice that respiratory responses to inhaled isocyanates depend on prior frequency and concentration of dermal sensitisation.19–21 25–30 In hairdressers, occupational skin diseases such as dermatitis have been described in those with OA caused by persulfate salts.9–11 In most of these cases, dermal sensitisation occurred prior to the development of asthma. Previously, we showed that ammonium persulfate is a moderate dermal sensitisers, according to the local lymph node assay (LLNA).10

Vanoirbeek et al developed a mouse model of chemical-induced asthma in which dermal sensitisation is followed by a single challenge. The model reproduces several of the main characteristics of human occupational asthma, namely the occurrence of an early ventilatory response, non-specific AHR and airway inflammation.19–21 The fact that AP responded positively in this model is a further validation of this model of chemical-induced asthma. In addition, we showed that lymphocytes responded directly on in vitro AP stimulation in an LPT. In our previous experiments we were not able to verify sensitisation in vitro because toluene diisocyanate (TDI) is not stable in an aqueous system. In our previous experiments we were not able to verify sensitisation in vitro because toluene diisocyanate (TDI) is not stable in an aqueous system. In our previous experiments we were not able to verify sensitisation in vitro because toluene diisocyanate (TDI) is not stable in an aqueous system. In our previous experiments we were not able to verify sensitisation in vitro because toluene diisocyanate (TDI) is not stable in an aqueous system. In our previous experiments we were not able to verify sensitisation in vitro because toluene diisocyanate (TDI) is not stable in an aqueous system.

total IgE and T lymphocytes were shown to be involved in AP-induced OA. 8

The cellular composition of the BAL after AP sensitisation and challenge in our model is not entirely typical for an immunologically mediated asthmatic response, since there was mainly an increase in neutrophils but no increase in eosinophils or lymphocytes. Several research groups, including ourselves, already observed this type of neutrophilic inflammation in murine models of chemical-induced asthma. 20 22 32–34 Moreover, it has been established that, in humans, eosinophils are not always increased and that neutrophilia is also an important feature of OA. 14 35 Thus, asthma caused by low molecular weight chemicals can be separated into eosinophilic and non-eosphilic variants, with the latter predominating. 36 In a population of hairdressers, Moscato et al showed that persulfate salts used in hair bleaching products are important agents involved in the development of OA and rhinitis. Sputum eosinophilia was associated with more severe disease and greater bronchodilator development of OA and rhinitis. Sputum eosinophilia was associated with more severe disease and greater bronchodilator development of OA and rhinitis. Sputum eosinophilia was associated with more severe disease and greater bronchodilator development of OA and rhinitis. Sputum eosinophilia was associated with more severe disease and greater bronchodilator development of OA and rhinitis. Sputum eosinophilia was associated with more severe disease and greater bronchodilator development of OA and rhinitis.

In conclusion, we have shown that ammonium persulfate, after two dermal applications and only a single airway challenge, can induce features of human occupational asthma in a mouse model. These features include AHR, neutrophilic inflammation, increased levels of total serum IgE, and T and B cell-specific responses. The complete mechanisms of these reactions remain to be elucidated. The consequences of exposure to persulfates are logically mediated asthmatic response, since there was mainly a feature of OA. Therefore, OA must be considered.
